

API Security with Tyk: Request Throttling

Learn how request throttling in Tyk controls the speed of incoming API requests to prevent overload. It ensures backend stability by spacing out traffic bursts and enforcing real-time rate limits per user or key

Throttling

- Throttling enables requests which exceed their rate limit to be retried by the API Gateway
- The Gateway will retry the request a number of times until it either succeeds or fails too many times
- This process can reduce the number of rate limit error responses received by API Clients
- The throttling process is hidden from the API Client, as their connection is kept open during the throttling process

Throttling

Throttling can be configured on Keys and Policies by setting a throttling interval and retry limit:

- Interval: Number of seconds to wait between retries, defined by the `throttle_interval` property
- Retry limit: Number of retries to attempt, defined by the `throttle_retry_limit` property
- Policies can define separate throttling configurations for each API they grant access to

Setting the properties to -1 will disable throttling, which is the default setting

Throttling
